4.5A Step-Up DC/DC Converter

General Description
The RT8509A is a high performance switching Boost converter that provides a regulated supply voltage for active matrix thin film transistor (TFT) liquid crystal displays (LCDs).

The RT8509A incorporates current mode, fixed-frequency, pulse width modulation (PWM) circuitry with a built in N-MOSFET to achieve high efficiency and fast transient response.

The RT8509A has a wide input voltage range from 2.8V to 14V. In addition, the output voltage can be adjusted up to 24V via an external resistive voltage divider. The maximum peak current is limited to 4.5A (min.). Other features include adjustable soft-start, over-voltage protection, and over-temperature protection.

The RT8509A is available in the WDFN-12L 5x5 package.

Features
- 90% Efficiency
- Adjustable Output Up to 24V
- 2.8V to 14V Input Supply Voltage
- Input Supply Under-Voltage Lockout
- Fixed 1.2MHz Switching Frequency
- Adjustable Soft-Start
- \( V_{OUT} \) Over-Voltage Protection
- Over-Temperature Protection
- Thin 12-Lead WDFN Package
- RoHS Compliant and Halogen Free

Applications
- GIP TFT-LCD Panels

Function Block Diagram

Operation

The RT8509A is a high-performance step-up DC/DC converter that provides a regulated and high precision supply voltage. It incorporates current mode, fixed-frequency, pulse-width modulation (PWM) circuitry with a built-in N-Channel power MOSFET to achieve high efficiency and fast transient response. The device features an adjustable soft start time using an external soft-start capacitor to reduce in-rush current.
Absolute Maximum Ratings  (Note 1)

- LX to GND -0.3V to 28V
- VIN, EN to GND -0.3V to 16.5V
- Other Pins -0.3V to 6.5V
- Power Dissipation, PD @ TA = 25°C
  WDFN-12L 5x5 3.38W
- Package Thermal Resistance (Note 2)
  WDFN-12L 5x5, θJA 29.5°C/W
  WDFN-12L 5x5, θJC 7.5°C/W
- Junction Temperature 150°C
- Storage Temperature Range -65°C to 150°C
- Lead Temperature (Soldering, 10sec.) 260°C
- ESD Susceptibility (Note 3)

**Note 1.** Stresses beyond those listed "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

**Note 2.** \(\theta_{JA}\) is measured at \(T_A = 25^\circ C\) on a high effective thermal conductivity four-layer test board per JEDEC 51-7. \(\theta_{JC}\) is measured at the exposed pad of the package.

**Note 3.** Devices are ESD sensitive. Handling precaution is recommended.

**Note 4.** The device is not guaranteed to function outside its operating conditions.

Application Information

The RT8509A is a high performance step-up DC/DC converter that provides a regulated supply voltage for panel source driver ICs. The RT8509A incorporates current mode, fixed frequency, Pulse Width Modulation (PWM) circuitry with a built-in N-MOSFET to achieve high efficiency and fast transient response. The internal driver power is supplied from the VOUT pin and that will increase efficiency when low input voltage condition. The following content contains detailed description and information for component selection.

Boost Regulator

The RT8509A is a current mode Boost converter integrated with a 24V/5A power switch, covering a wide VIN range from 2.8V to 14V. It performs fast transient responses to generate source driver supplies for TFT-LCD display. The high operation frequency allows the use of smaller components to minimize the thickness of the LCD panel. The output voltage can be adjusted by setting the resistive voltage-divider sensing at the FB pin. The error amplifier varies the COMP voltage by sensing the FB pin to regulate the output voltage. For better stability, the slope compensation signal summed with the current sense signal will be compared with the COMP voltage to determine the current trip point and duty cycle. The Boost minimum gain ratio depends on minimum on-time. It’s suggested that VOUT higher than 1.2 x VIN for better performance.

Soft-Start

The RT8509A provides soft-start function to minimize the inrush current. When powered on, an internal constant current charges an external capacitor. The rising voltage rate on the COMP pin is limited from VSS = 0V to 1.24V and the inductor peak current will also be limited at the same time. When powered off, the external capacitor will be discharged until the next soft-start time.

The soft-start function is implemented by the external capacitor with a 5μA constant current charging to the soft-start capacitor. Therefore, the capacitor should be large enough for output voltage regulation. A typical value for soft-start capacitor range is from 10nF to 100nF.

If CSS < 220pF, the internal soft-start function will be turned on and period time is approximately 1ms.

Output Voltage Setting

The regulated output voltage is shown as the following equation:

\[ V_{OUT} = V_{REF} \times \left(1 + \frac{R_1}{R_2}\right) \]

where \( V_{REF} = 1.25V \) (typ.)

The recommended value for R2 should be at least 10kΩ without some sacrificing. Place the resistive voltage divider as close as possible to the chip to reduce noise sensitivity.

Loop Compensation

The voltage feedback loop can be compensated with an external compensation network consisting of R3. Choose R3 to set high frequency integrator gain for fast transient response and C1 to set the integrator zero to maintain loop stability. For typical application, \( V_{IN} = 5V \), \( V_{OUT} = 13.6V \), \( C_{OUT} = 4.7\mu F \times 3 \), \( L_1 = 4.7\mu H \), while the recommended value for compensation is as follows:

\[ R_3 = 56k\Omega \]

\[ C_1 = 1nF \]

Over-Current Protection

The RT8509A Boost converter has over-current protection to limit the peak inductor current. It prevents the inductor and diode from damage due to large current. During the On-time, once the inductor current exceeds the current limit, the internal LX switch turns off immediately and shortens the duty cycle. Therefore, the output-voltage drops if the over current condition occurs. The current limit is also affected by the input voltage, duty cycle, and inductor value.

Over-Temperature Protection

The RT8509A Boost converter has thermal protection function to prevent the chip from overheating. When the junction temperature exceeds 155°C, the function shuts down the device. Once the device cools down by approximately 10°C, it will automatically restart to normal operation. To guarantee continuous operation, do not operate over the maximum junction temperature rating of 125°C.
Inductor Selection
The inductance depends on the maximum input current. As a general rule, the inductor ripple current range is 20% to 40% of the maximum input current. If 40% is selected as an example, the inductor ripple current can be calculated according to the following equations:

\[
I_{\text{RIPPLE}} = 0.4 \times I_{\text{IN(MAX)}}
\]

where \(\eta\) is the efficiency of the converter, \(I_{\text{IN(MAX)}}\) is the maximum input current, and \(I_{\text{RIPPLE}}\) is the inductor ripple current. The input peak current can then be obtained by adding the maximum input current with half of the inductor ripple current as shown in the following equation:

\[
I_{\text{PEAK}} = 1.2 \times I_{\text{IN(MAX)}}
\]

Note that the saturated current of the inductor must be greater than \(I_{\text{PEAK}}\). The inductance can eventually be determined according to the following equation:

\[
L = \frac{\eta \times (V_{\text{IN}})^2 \times (V_{\text{OUT}} - V_{\text{IN}})}{0.4 \times (V_{\text{OUT}})^2 \times I_{\text{OUT(MAX)}} \times f_{\text{OSC}}}
\]

where \(f_{\text{OSC}}\) is the switching frequency. For better system performance, a shielded inductor is preferred to avoid EMI problems.

Diode Selection
Schottky diodes are chosen for their low forward voltage drop and fast switching speed. When selecting a Schottky diode, important parameters such as power dissipation, reverse voltage rating, and pulsating peak current should all be taken into consideration. A suitable Schottky diode's reverse voltage rating must be greater than the maximum output voltage and its average current rating must exceed the average output current. Last of all, the chosen diode should have a sufficiently low leakage current level, since it will increase with temperature.

Output Capacitor Selection
The output ripple voltage is an important index for estimating chip performance. This portion consists of two parts. One is the product of the inductor current with the ESR of the output capacitor, while the other part is formed by the charging and discharging process of the output capacitor. As shown in Figure 1, \(\Delta V_{\text{OUT1}}\) can be evaluated based on the ideal energy equalization. According to the definition of \(Q\), the \(Q\) value can be calculated as the following equation:

\[
Q = \frac{1}{2} \times \frac{V_{\text{IN}} + \frac{1}{2} \Delta I_{L}}{V_{\text{OUT}}} + \left( \frac{I_{\text{IN}} - \frac{1}{2} \Delta I_{L}}{V_{\text{OUT}}} \right) \times \frac{1}{f_{\text{OSC}}} = \frac{C_{\text{OUT}}}{\eta} \times \Delta V_{\text{OUT1}}
\]

where \(f_{\text{OSC}}\) is the switching frequency, and \(\Delta I_{L}\) is the inductor ripple current. Bring \(C_{\text{OUT}}\) to the left side to estimate the value of \(\Delta V_{\text{OUT1}}\) according to the following equation:

\[
\Delta V_{\text{OUT1}} = \frac{D \times I_{\text{OUT}}}{\eta \times C_{\text{OUT}} \times f_{\text{OSC}}}
\]

where \(D\) is the duty cycle and \(\eta\) is the Boost converter efficiency. Finally, taking ESR into account, the overall output ripple voltage can be determined by the following equation:

\[
\Delta V_{\text{OUT}} = I_{\text{IN}} \times \text{ESR} + \frac{D \times I_{\text{OUT}}}{\eta \times C_{\text{OUT}} \times f_{\text{OSC}}} \times \frac{1}{f_{\text{OSC}}}
\]

The output capacitor, \(C_{\text{OUT}}\), should be selected accordingly.

Input Capacitor Selection
Low ESR ceramic capacitors are recommended for input capacitor applications. Low ESR will effectively reduce the input voltage ripple caused by switching operation. A 10μF capacitor is sufficient for most applications.
Nevertheless, this value can be decreased for lower output current requirement. Another consideration is the voltage rating of the input capacitor which must be greater than the maximum input voltage.

**Thermal Considerations**

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula:

\[
P_{D(MAX)} = \frac{T_{J(MAX)} - T_A}{\theta_{JA}}
\]

where \( T_{J(MAX)} \) is the maximum junction temperature, \( T_A \) is the ambient temperature, and \( \theta_{JA} \) is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is 125°C. The junction to ambient thermal resistance, \( \theta_{JA} \), is layout dependent. For WDFN-12L 5x5 packages, the thermal resistance, \( \theta_{JA} \), is 29.5°C/W on a standard JEDEC 51-7 four-layer thermal test board. The maximum power dissipation at \( T_A = 25°C \) can be calculated by the following formula:

\[
P_{D(MAX)} = \frac{(125°C - 25°C)}{(29.5°C/W)} = 3.38W \text{ for WDFN-12L 5x5 package}
\]

The maximum power dissipation depends on the operating ambient temperature for fixed \( T_{J(MAX)} \) and thermal resistance, \( \theta_{JA} \). The derating curve in Figure 2 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

### Layout Considerations

For high frequency switching power supplies, the PCB layout is important to get good regulation, high efficiency and stability. The following descriptions are the guidelines for better PCB layout.

- For good regulation, place the power components as close as possible. The traces should be wide and short enough especially for the high current output loop.
- The feedback voltage divider resistors must be near the feedback pin. The divider center trace must be shorter and the trace must be kept away from any switching nodes.
- The compensation circuit should be kept away from the power loops and be shielded with a ground trace to prevent any noise coupling.
- Minimize the size of the LX node and keep it wide and shorter. Keep the LX node away from the FB.
- The exposed pad of the chip should be connected to a strong ground plane for maximum thermal consideration.

![Figure 2. Derating Curve of Maximum Power Dissipation](image)
Figure 3. PCB Layout Guide

The compensation circuit should be kept away from the power loops and should be shielded with a ground trace to prevent any noise coupling.

Locate the C2 as close to the VIN pin as possible.

Place the power components as close as possible. The traces should be wide and short, especially for the high-current loop.

The feedback voltage-divider resistors must near the feedback pin. The divider center trace must be shorter and avoid the trace near any switching nodes.

More GND via and layout area for better thermal performance.

The switching trace should be wide and short, especially for the high-current loop.
Outline Dimension

Note: The configuration of the Pin #1 identifier is optional, but must be located within the zone indicated.
