12A, 17V, High Efficiency Synchronous Step-Down Converter

General Description
The RTQ2822A/B is a high-performance, synchronous step-down converter that can deliver up to 12A output current with an input supply voltage range of 4.5V to 17V. The device integrates low $R_{DS(ON)}$ power MOSFETs, accurate 0.6V reference and an integrated diode for bootstrap circuit to offer a very compact solution.

The RTQ2822A/B adopts Advanced Constant On-Time (ACOT®) control architecture that provides ultrafast transient response and further reduce the external-component count. In steady states, the ACOT® operates in nearly constant switching frequency over line, load and output voltage ranges and makes the EMI filter design easier.

The device offers a variety of functions for more design flexibility. The selectable switching frequency, current limit level and PWM operation modes makes the RTQ2822A/B easy-to-use over wide application range. Independent enable control input pin and power good indicator are also provided for easy sequence control. To control the inrush current during the startup, the device provides a programmable soft start-up by an external capacitor connected to the SS pin. Fully protection features are also integrated in the device including the cycle-by-cycle current limit, OVP, UVP, input UVLO and OTP.

The RTQ2822A/B is available in a thermally enhanced VQFN-18L 3.5x3.5 (FC) package.

Features
- 4.5V to 17V Input Voltage Range
- Integrated 9.8mΩ/4.5mΩ MOSFETs
- 0.6V ±1% Voltage Reference
- Adjustable Output Voltage from 0.6V to 5.5V
- Supports Ceramic Output Capacitor
- ACOT® Control for Fast Transient Response
- Selectable Switching Frequency (400kHz/800kHz/1200kHz)
- Selectable Current Limit Level
- Power Good Indicator
- Programmable Soft-Start Time with a Default 1ms
- Monotonic Start-Up into Pre-Biased Outputs
- 18-Lead VQFN (FC) Package

Applications
- Server, Storage and Network Equipment
- Telecom Infrastructure
- Point of Load (POL) Power Modules
- High Density DC-DC Converters
- High End Digital TV

Ordering Information

RTQ2822A/B

- Pin 1 Orientation***
  - (2) : Quadrant 2, Follow EIA-481-D
  - RTQ2822A only

- Package Type
  - QVF : VQFN-18L 3.5x3.5 (FC) (V-Type)

- Lead Plating System
  - G : Green (Halogen Free and Pb Free)

- Enable Pin
  - A : Internal Pull High
  - B : Internal Pull Low

Note:

***Empty means Pin1 orientation is Quadrant 1

Richtek products are:

- RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- Suitable for use in SnPb or Pb-free soldering processes.

**Operation**

The RTQ2822A/B is a high efficiency synchronous step-down converter utilizing the proprietary Advanced Constant On-Time (ACOT®) control architecture. The ultrafast ACOT® control enables the use of small capacitance to save the PCB size.

During normal operation, the internal high-side power switch (HSFET) turns on for a fixed interval determined by a one-shot timer at the beginning of each clock cycle. When the HSFET turns off, the low-side power switch (LSFET) turns on. Due to the output capacitor ESR, the voltage ripple on the output has similar shape as the inductor current. Via the feedback resistor network, this voltage ripple compared with the internal reference. When the minimum off-time one-shot (310ns, max.) has timed out and the inductor current is below the current limit threshold, the One-shot is triggered again if the feedback voltage falls below the feedback reference voltage (0.6V, typ.). To achieve stable operation with low-ESR ceramic output capacitors, an internal ramp signal is added to the feedback reference voltage to simulate the output voltage ripple. ACOT® control architecture features ultrafast transient response. When a load is suddenly increased, the output voltage drops quickly, and almost immediately, a new On-time is triggered, and inductor current rises again.

Traditional COT controller implements the on-time to be inversely proportional to input voltage and directly proportional to the output voltage to achieve pseudo-fixed frequency over the input voltage range. But even with defined input and output voltages, a fixed ON time will mean that frequency will have to increase at higher load levels to compensate for the power losses in the MOSFETs and Inductor. ACOT® control further added a frequency locked loop system, which slowly adjusts the ON time to compensate the power losses, without influencing the fast transient behavior of the COT topology.

**Power and Bias Supply**

The VIN pins on the RTQ2822A/B are used to supply voltage to the drain terminal of the internal HSFET. These pins also supply bias voltage for an internal regulator that generates 4.7V at VCC. The voltage on VCC pin is used for internal chip bias and gate drive for the LSFET. The gate drive for the HSFET is supplied by a floating supply (CBOOT) between the BOOT and SW pins, which is charged by an internal synchronous diode from VCC. In addition, an internal charge pump maintains the CBOOT voltage is sufficient to turn-on the HSFET.

To improve efficiency and limit power dissipation in the VIN, an external voltage that is above the LDO’s internal output voltage can override the internal LDO. When using an external bias on the VCC rail, any power-up and power-down sequencing can be applied but it is important to understand that if there is a discharge path on the VCC rail that can pull a current higher than the internal LDO’s current limit from the VCC, then the VCC drops below the UVLO falling threshold and thereby shutting down the output of the RTQ2822A/B.

**Enable, Start-Up, Shutdown and UVLO**

The RTQ2822A/B implements Under-Voltage Lock Out protection (UVLO) to prevent operation without fully turn-on the internal power MOSFETs. The UVLO monitors the internal VCC regulator voltage. When the VCC voltage is lower than UVLO threshold voltage, the device stops switching. UVLO is non-latching protection.

The EN pin is provided to control the device turn-on and turn-off. When EN pin voltage is above the turn-on threshold (VENH), the device starts switching and when the EN pin voltage falls below the turn-off threshold (VENL) it stops switching. The EN pin of the RTQ2822A has internally pull-up with current source. However, the RTQ2822B internally week pull-down the EN pin.

When appropriate voltages are present on the VIN, VCC, and EN pins, the RTQ2822A/B will begin switching and initiate a soft-start ramp of the output voltage. An internal soft-start ramp of 1.045ms will limit the ramp rate of the output voltage to prevent excessive input current during start-up. If a longer ramp time is desired, a capacitor can be placed from the SS pin to ground. The 6μA current that is sourced from the SS pin will create a smooth voltage ramp on the capacitor. If this external ramp rate is slower than the internal 1.045ms soft-start, the output voltage will be limited by the ramp rate on the SS pin instead.
Once both of the external and internal soft-start ramps have exceeded 0.7V, the output voltage will be in regulation. The typical external soft start time can be calculated by the equation below.

\[
C_{SS} \ (\text{nF}) = \frac{t_{SS} \ (\text{ms}) \times I_{SS} \ (\mu\text{A})}{V_{REF} \ (\text{V})}
\]

Where \( I_{SS} = 6\mu\text{A}, V_{REF} = 0.6\text{V} \)

When the \( V_{EN} \) is lower than \( V_{ENL} \), the SS pin voltage is reset to GND.

**Pre-Bias**

If there is a residual voltage on output voltage before start-up, both of the internal HSFET and LSFET are prohibited switching until the soft start ramp is higher than feedback voltage. When the soft start ramp cross above the feedback voltage, switching will begin and the output voltage will smoothly rise from the pre-biased level to its regulated target.

**Mode Selection for Light Load Operation, Switching Frequency and Current Limit**

MODE pin offers 12 different states of operation as a combination of Light Load operation, Switching Frequency and Current Limit. As shown in the Figure 3, use a resistor divider from VCC to AGND can set the MODE pin voltage. It is important that the voltage for the MODE pin is derived from the VCC rail only since internally this voltage is referenced to detect the MODE option. The device reads the voltage on the MODE pin during start-up and latches onto one of the MODE options listed below in Table 1. The MODE pin setting can be reset only by a VIN power cycling. The two resistors (\( R_{M1} \) and \( R_{M2} \)) are suggested to use 1% resistors.

![Figure 3. MODE Connection](image-url)
Light Load Operation

At low load current, the inductor current can drop to zero and become negative. This is detected by internal zero-current-detect circuitry which utilizing the LSFET $R_{DS(ON)}$ to sense the inductor current. The LSFET is turned off when the inductor current drops to zero, resulting in discontinuous operation (DCM). Both power MOSFETs will remain off with the output capacitor supplying the load current until the feedback voltage falls below the feedback reference voltage. DCM operation maintains high efficiency at light load, while setting MODE to Forced PWM (FCCM) operation helps meet tight voltage regulation accuracy requirements.

Switching Frequency, Minimum On-Time and Minimum Off-Time

The RTQ2822A/B offers three different switching frequency of 400kHz, 800kHz and 1200kHz by setting the MODE pin voltage. Selection of the operating frequency is a trade-off between efficiency and component size. High frequency operation allows the use of smaller inductor and capacitor values. Operation at lower frequencies improves efficiency by reducing internal gate charge and transition losses, but requires larger inductance values and/or capacitance to maintain low output ripple voltage.

An additional constraint on operating frequency is the minimum controllable on-time and off-time. The minimum on-time is the smallest duration of time in which the high-side power MOSFET (HSFET) can be in its “on” state. This time is typically 54ns. In continuous mode operation, the minimum duty cycle can be estimated by ignoring component losses as follows

$$D_{MIN} = \frac{f_{SW} \times t_{ON\_MIN}}{54}$$

Where $t_{ON\_MIN}$ is the minimum on-time. As the equation shows, reducing the operating frequency will alleviate the minimum duty cycle constraint.

The minimum off-time, $t_{OFF\_MIN}$, is the smallest amount of time that the RTQ2822A/B is capable of turning on the low-side power MOSFET (LSFET), tripping the current comparator and turning the power MOSFET back off. This time is 310ns (max.). The minimum off-time limit imposes a maximum duty cycle of $t_{ON} / (t_{ON} + t_{OFF\_MIN})$.

Current Limit and Output Under-Voltage Protection

As shown in Table 1, the RTQ2822A/B can operate at two different current limits $I_{LIM\_1}$ and $I_{LIM\_2}$ to support an output continuous current of 12A and 10A respectively. The device cycle-by-cycle compares the valley current of the inductor against the current limit threshold, hence the output current will be half the ripple current higher than the valley current.

The inductor current level is monitored by measuring the low-side MOSFET voltage between the SW pin and GND.

</tbody>
</table>
which is proportional to the switch current, during the on-time of LSFET. To improve the current measurement accuracy, temperature compensation is added internally. If the measured drain to source voltage of the LSFET is above the voltage proportional to current limit, the LSFET stays on until the current level becomes lower than the OCL level which reduces the output current available. When the current is limited the output voltage tends to drop because the load demand is higher than what the converter can support.

When the output voltage falls below Output UVP Threshold (V_{UVP}), the UVP comparator detects it and shuts down the device to avoid the excessive heat. If the UVP condition remains for a period of time, a soft-start sequence for auto-recovery will be initiated. It is shown in Figure 4. When the overcurrent condition is removed, the output voltage returns to the regulated value.

![Figure 4. Current Limit and UVP](image)

Similar to the forward overcurrent, the reverse current protection is realized by monitoring the current across the low-side MOSFET. When the LSFET current reaches negative current limit, the synchronous rectifier is turned off. This limits the ability of the regulator to actively pull-down on the output.

Note. In order to prevent the NOC is triggered on light load operation, the inductor valley current should be designed to higher than I_{LM_NEG} when the MODE selection is FCCM.

**Power-Good Output**

The PGOOD pin is an open-drain power-good indication which is connected to an external voltage source through a pull-up resistor. The power-good function is activated after soft-start is finished and is controlled by the feedback signal V_{FB}. During soft-start, PGOOD is actively held low and only allowed to transition high after soft-start is over. If V_{FB} rises above a power-good threshold V_{TH_PGLH} (typically 93% of the target value), the PGOOD pin will be in high impedance and V_{PGOOD} will be held high after a certain delay elapsed. When V_{FB} drops by a V_{FB} falling hysteresis ΔV_{TH_PGLH} (typically 9% of the target value) or exceeds V_{FB} rising threshold V_{TH_PGLH} (typically 116% of the target value), the PGOOD pin will be pulled low. For V_{FB} above V_{FB} falling hysteresis, V_{PGOOD} will be pulled high again when V_{FB} drops by a power-good hysteresis ΔV_{TH_PGLH} (typically 9% of the target value). Once being started-up, if any protection is triggered (UVP and OTP) or EN is from high to low, PGOOD will be pulled to GND. The internal open-drain pull down device with 250Ω resistance will pull the PGOOD pin low. To prevent unwanted PGOOD glitches during transients or dynamic VOUT changes, the RTQ2822A/B's PGOOD falling edge includes a blanking delay of approximately 1μs.

![Figure 5. The Logic of PGOOD](image)

**Output Over-Voltage Protection (OVP)**

The RTQ2822A/B provides an over-voltage protection (OVP). If the FB voltage (V_{FB}) rises above 121% of the internal reference voltage, the over-voltage protection is triggered, the discharging switch from SW to GND is turned on to discharge output voltage.

**Over-Temperature Protection (OTP)**

The RTQ2822A/B monitors the internal die temperature. If this temperature exceeds the thermal shutdown threshold value (T_{SD}, typically 160°C), the RTQ2822A/B stops switching with SS reset to ground and an internal discharge switch turns on to quickly discharge the output.
voltage. During start up, if the device temperature is higher than 160°C the device does not start switching. The device re-starts switching when the temperature drops more than 15°C (typ.) but the MODE settings are not re-loaded again. If the temperature continues to rise and above LDO thermal shutdown threshold ($T_{SD,LDO}$, typically 171°C), the converter shuts down completely.

Note that the over temperature protection is intended to protect the device during momentary overload conditions. The protection is activated outside of the absolute maximum range of operation as a secondary fail-safe and therefore should not be relied upon operationally. Continuous operation above the specified absolute maximum operating junction temperature may impair device reliability or permanently damage the device.

**Output Voltage Discharge**

An internal 500Ω discharge switch that discharges the $V_{OUT}$ through SW node during any fault events like OVP, UVP, OTP, VCC voltage below UVLO and when the EN pin voltage ($V_{EN}$) is below the turn-on threshold.

**Note 1.** Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

**Note 2.** $\theta_{JA}$ is measured in the natural convection at $T_A = 25^\circ$C on a Four-layer Richtek Evaluation Board. $\theta_{JC}$ is measured at the top of the package.

**Note 3.** Devices are ESD sensitive. Handling precaution is recommended.

**Note 4.** The device is not guaranteed to function outside its operating conditions.
Typical Application Circuit

Note:
(1) All the input and output capacitors are the suggested values, referring to the effective capacitances, subject to any derating effect, like a DC bias.

(2) Considering the noise immunity when the C_F is soldered on PCB, it is necessary to add $R_T = 100\,\Omega$ between feedback network and chip FB pin.

Application Information

A general RTQ2822A/B application circuit is shown in typical application circuit section. External component selection is largely driven by the load requirement and begins with the selection of the operating frequency and light load operating mode by setting the MODE pin voltage. Next, the inductor L is chosen and then the input capacitor CIN, the output capacitor COUT, the internal regulator capacitor CVCC, and the bootstrap capacitor CBOOT, can be selected. Next, feedback resistors are selected to set the desired output voltage. Finally, the remaining optional external components can be selected for functions such as the EN and UVLO threshold, external soft-start time, and PGOOD.

Switching Frequency and MODE Selection

Switching Frequency, current limit and switching mode (DCM or FCCM) are set by a voltage divider from, and is only from, VCC to GND connected to the MODE pin. Selection of the operating frequency is a trade-off between efficiency and component size. High frequency operation allows the use of smaller inductor and capacitor values. Operation at lower frequencies improves efficiency by reducing internal gate charge and transition losses, but requires larger inductance values and/or capacitance to maintain low output ripple voltage.

Inductor Selection

The inductor selection trade-offs among size, cost, efficiency, and transient response requirements. Generally, three key inductor parameters are specified for operation with the device: inductance value (L), inductor saturation current (ISAT), and DC resistance (DCR).

A good compromise between size and loss is a 30% peak-to-peak ripple current ΔIL to the IC rated current. The switching frequency, input voltage, output voltage, and selected inductor ripple current determines the inductor value as follows:

\[ L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times \Delta L} \]

Larger inductance values result in lower output ripple voltage and higher efficiency, but a slightly degraded transient response. Lower inductance values allow for smaller case size, but the increased ripple lowers the effective current limit threshold and increases the AC losses in the inductor. To enhance the efficiency, choose a low-loss inductor having the lowest possible DC resistance that fits in the allotted dimensions. The inductor value determines not only the ripple current but also the load-current value at which DCM/CCM switchover occurs.

The inductor selected should have a saturation current rating greater than the peak current limit of the device. The core must be large enough not to saturate at the peak inductor current (I_{PEAK}):

\[ \Delta L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times L} \]

\[ I_{PEAK} = I_{OUT_{MAX}} + \frac{1}{2} \Delta L \]

The current flowing through the inductor is the inductor ripple current plus the output current. During power up, faults or transient load conditions, the inductor current can increase above the calculated peak inductor current level calculated above. In transient conditions, the inductor current can increase up to the switch current limit of the device. For this reason, the most conservative approach is to specify an inductor with a saturation current rating equal to or greater than the switch current limit rather than the peak inductor current.

Input Capacitor Selection

Input capacitance, CIN, is needed to filter the pulsating current at the drain of the high-side power MOSFET. CIN should be sized to do this without causing a large variation in input voltage. The peak-to-peak voltage ripple on input capacitor can be estimated as equation below:

\[ \Delta V_{CIN} = D \times I_{OUT} \times \frac{1 - D}{C_{IN} \times f_{SW}} + I_{OUT} \times ESR \]

Where

\[ D = \frac{V_{OUT}}{V_{IN} \times \eta} \]

For ceramic capacitors, the equivalent series resistance (ESR) is very low, the ripple which is caused by ESR can be ignored, and the minimum input capacitance can be
In addition, the input capacitor needs to have a very low ESR and must be rated to handle the worst-case RMS input current of:

$$I_{RMS} \approx I_{OUT\_MAX} \times \frac{V_{OUT}}{V_{IN}} \times \sqrt{\frac{V_{IN}}{V_{OUT}}} - 1$$

It is commonly to use the worse $$I_{RMS} \approx \frac{I_{OUT\_MAX}}{2}$$ at $$V_{IN} = 2V_{OUT}$$ for design. Note that ripple current ratings from capacitor manufacturers are often based on only 2000 hours of life which makes it advisable to further de-rate the capacitor, or choose a capacitor rated at a higher temperature than required.

Several capacitors may also be paralleled to meet size, height and thermal requirements in the design. For low input voltage applications, sufficient bulk input capacitance is needed to minimize transient effects during output load changes.

Ceramic capacitors are ideal for switching regulator applications due to its small, robust and very low ESR. However, care must be taken when these capacitors are used at the input. A ceramic input capacitor combined with trace or cable inductance forms a high quality (under damped) tank circuit. If the RTQ2822A/B circuit is plugged into a live supply, the input voltage can ring to twice its nominal value, possibly exceeding the device's rating. This situation is easily avoided by placing the low ESR ceramic input capacitor in parallel with a bulk capacitor with higher ESR to damp the voltage ringing.

The input capacitor should be placed as close as possible to the VIN pins, with a low inductance connection to the PGND of the IC. In addition to a larger bulk capacitor, two small ceramic capacitors of 0.1μF should be placed close to the part; one at the VIN1/PGD1 pins and a second at VIN2/PGD2 pins. These capacitors should be 0402 or 0603 in size.

### Output Capacitor Selection

The selection of C{sub OUT} is determined by considering to satisfy the voltage ripple, the transient loads and to ensure that control loop is stable. Loop stability can be checked by viewing the load transient response. The peak-to-peak output ripple, $$\Delta V_{OUT}$$, is characterized by two components, which are ESR ripple $$\Delta V_{P-P\_ESR}$$ and capacitive ripple $$\Delta V_{P-P\_C}$$, can be expressed as below:

$$\Delta V_{OUT} = \Delta V_{P-P\_ESR} + \Delta V_{P-P\_C}$$

$$\Delta V_{P-P\_ESR} = \Delta IL \times R_{ESR}$$

$$\Delta V_{P-P\_C} = \frac{\Delta IL}{8 \times C_{OUT} \times t_{SW}}$$

Where the $$\Delta IL$$ is the peak-to-peak inductor ripple current and $$R_{ESR}$$ is the equivalent series resistance of C{sub OUT}. The output ripple is highest at maximum input voltage since $$\Delta IL$$ increases with input voltage. Multiple capacitors placed in parallel may be needed to meet the ESR and RMS current handling requirements.

Regarding to the transient loads, the V{sub SAG} and V{sub SOAR} requirement should be taken into consideration for choosing the output capacitance value. The amount of output sag is a function of the maximum duty factor, which can be calculated from the on-time and minimum off-time.

$$t_{ON} = \frac{V_{OUT}}{V_{IN} \times t_{SW}}$$

$$D_{MAX} = \frac{t_{ON}}{t_{ON} + t_{OFF\_MIN}}$$

The worst-case output sag voltage can be determined by:

$$\Delta V_{OUT\_SAG} = \frac{L \times (L\_PEAK)^2}{2 \times C_{OUT} \times (V_{IN} \times D_{MAX} - V_{OUT})}$$

The amount of overshoot due to stored inductor energy when the load is removed can be calculated as:

$$\Delta V_{OUT\_SOAR} = \frac{L \times (L\_PEAK)^2}{2 \times C_{OUT} \times V_{OUT}}$$

Ceramic capacitors have very low equivalent series resistance (ESR) and provide the best ripple performance.
Be careful to consider the voltage coefficient of ceramic capacitors when choosing the value and case size. Most ceramic capacitors lose 50% or more of their rated value when used near their rated voltage.

**Internal VCC Regulator**

Good bypassing at VCC pin is necessary to supply the high transient currents required by the power MOSFET gate drivers. Place a low ESR MLCC capacitor with capacitance $\geq 4.7\mu F$ (or effective capacitance $\geq 1.5\mu F$) as close as possible to VCC pin, the rated voltage of $C_{VCC}$ should be higher than 10V with 0603 or 0402 in size. Applications with high input voltage and high switching frequency will increase die temperature because of the higher power dissipation across the LDO. Do not connect VCC to provide power to other devices or loads.

**HSFET Bootstrap Driver Supply**

The bootstrap capacitor ($C_{BOOT}$) between BOOT pin and SW pin is used to create a voltage rail above the applied input voltage, $V_{IN}$. Specifically, the bootstrap capacitor is charged through an internal MOSFET switch to a voltage equal to approximately $V_{VCC}$ each time the LSFET is turned on. The charge on this capacitor is then used to supply the required current during the remainder of the switching cycle.

The selection of $C_{BOOT}$ considers the voltage variation allowed on the high-side MOSFET driver after turn-on. Choose $\Delta V_{BOOT}$ such that the available gate-drive voltage is not significantly degraded when determining $C_{BOOT}$. A typical range of $\Delta V_{BOOT}$ is 100mV to 300mV. The bootstrap capacitor should be a low-ESR ceramic capacitor. For most applications a 0.1$\mu F$ ceramic capacitor with X5R or better grade dielectric is recommended. The capacitor should have a 10V or higher voltage rating.

It is recommended to add an external bootstrap Schottky diode between an external 5V voltage supply and the BOOT pin as shown in Figure 7 to improve enhancement of the internal MOSFET switch and improve efficiency when the input voltage, $V_{IN}$, is below 5V. The bootstrap Schottky diode can be a low-cost one, such as BAT54. The external 5V can be a fixed 5V voltage supply from the system, or a 5V output voltage generated by the RTQ2822A/B. Note that the BOOT voltage $V_{BOOT}$ must be lower than 5.5V. The figure 8 shows the efficiency with/without an external 5V supply.

![Figure 7. External Bootstrap Diode and Resistor at the BOOT Pin](image)

![Figure 8. Efficiency Comparison with/without external 5V supply](image)

EMI issue is worse when the switch is turned on rapidly due to high di/dt noises induced. In some cases, it is desirable to reduce EMI further, even at the expense of some additional power dissipation. The turn-on rate of the high-side switch can be slowed by placing a small (< 20$\Omega$) resistor between the BOOT pin and the external bootstrap capacitor. This will slow down the rates of the high-side switch turn-on and the rise of $V_{SW}$. The recommended application circuit is shown in Figure 8, which includes an external bootstrap diode for charging the bootstrap capacitor and a bootstrap resistor $R_{BOOT}$ being placed between the BOOT pin and the capacitor/diode connection.
Output Voltage Programming
The output voltage is set by an external resistive divider according to the following equation:

\[ V_{\text{OUT}} = V_{\text{REF}} \times \left(1 + \frac{R_1}{R_2}\right) \]

Figure 9. Output Voltage Setting

For a given \( R_2 \), the resistance of \( R_1 \) can be calculated as below:

\[ R_1 = \frac{R_2 \times (V_{\text{OUT}} - V_{\text{REF}})}{V_{\text{REF}}} \]

1% resistors are recommended to maintain output voltage accuracy. The total resistance of the FB resistor divider should be selected to be as large as possible when good low load efficiency is desired: The resistor divider generates a small load on the output, which should be minimized to optimize the quiescent current at low loads.

Place resistors \( R_1 \) and \( R_2 \) very close to the FB pin to minimize PCB trace length and noise. Great care should be taken to route the FB trace away from noise sources, such as the inductor or the SW trace. To improve frequency response, a feed-forward capacitor (\( C_{\text{FF}} \)) may be used.

Feedforward Capacitor (\( C_{\text{FF}} \))
The RTQ2822A/B is optimized for low duty-cycle applications and the control loop is stable with low ESR ceramic output capacitors. In higher duty-cycle applications (higher output voltages or lower input voltage), the internal ripple signal will increase in amplitude. Before the ACOT® control loop can react to an output voltage fluctuation, the voltage change on the feedback signal must exceed the internal ripple amplitude. Because of the large internal ripple in this condition, the response may become too slow, and may show an under-damped response. This can cause some ringing in the output, and is especially visible at higher output voltage applications like 12V to 5V where duty-cycle is high and the feedback network attenuation is large, adding to the delay. As shown in

Figure 10, adding a feedforward capacitor (\( C_{\text{FF}} \)) across the upper feedback resistor is recommended. This increases the damping of the control system.

Figure 10. Feedback Loop with Feedforward Capacitor

Loop stability can be checked by viewing the load transient response. A load step with a speed that exceeds the converter bandwidth must be applied. For ACOT®, loop bandwidth can be in the order of 100 to 200kHz, so a load step with 500ns maximum rise time (\( \frac{\text{di}}{\text{dt}} \approx 2\text{A/μs} \)) ensures the excitation frequency is sufficient. It is important that the converter operates in PWM mode, outside the light load efficiency range, and below any current limit threshold. A load transient from 30% to 60% of maximum load is reasonable which is shown in Figure 11.

Figure 11. Example of Measuring the Converter BW by Fast Load Transient

\( C_{\text{FF}} \) can be calculated basing on below equation:

\[ C_{\text{FF}} = \frac{1}{2\pi \times \text{BW}} \times \sqrt{\frac{1}{R_1} \times \left(\frac{1}{R_1} + \frac{1}{R_2}\right)} \]

Figure 12. shows the transient performance with and without feedforward capacitor.
**Enable and Adjustable UVLO**

The EN pin controls the turn-on and turn-off of the device. When EN pin voltage is above the turn-on threshold (VENH), the device starts switching, and it stops when the EN pin voltage falls below the turn-off threshold (VENL). The EN pin of the RTQ2822A has internally pull-up with current source. However, the RTQ2822B internally week pull-down the EN pin. Figure 13. shows example if an enable time delay is required.

\[
R_{EN1} = \frac{V_{START} \times V_{ENL}}{I_{ENP1} \left(1 - \frac{V_{ENL}}{VENH}\right) + (I_{ENP2} - I_{ENP1})}
\]

\[
R_{EN2} = \frac{R_{EN1} \times V_{ENH}}{V_{START} + (R_{EN1} \times I_{ENP1}) - V_{ENH}}
\]

Where

- \(I_{ENP2} = 4.2\mu A\)
- \(I_{ENP1} = 2\mu A\)
- \(V_{ENL} = 1.104V\)
- \(V_{ENH} = 1.225V\)

**Thermal Consideration**

In many applications, the RTQ2822A/B does not generate much heat due to its high efficiency and low thermal resistance of its flip-chip QFN-18L 3.5x3.5 package. However, in applications which the RTQ2822A/B is running at a high ambient temperature, high input voltage and high
switching frequency, the generated heat may exceed the maximum junction temperature of the part.

The junction temperature should never exceed the absolute maximum junction temperature listed under Absolute Maximum Ratings, to avoid permanent damage to the device. If the junction temperature reaches approximately 160°C, the RTQ2822A/B stop switching the power MOSFETs until the temperature drops about 15°C cooler.

The maximum power dissipation can be calculated by the following formula:

\[ P_{D(MAX)} = \frac{\left( T_{J(MAX)} - T_A \right)}{\theta_{JA(EFFECTIVE)}} \]

Where

- \( T_{J(MAX)} \) is the maximum allowed junction temperature of the die. For recommended operating condition specifications, the maximum junction temperature is 125°C.
- \( T_A \) is the ambient operating temperature,
- \( \theta_{JA(EFFECTIVE)} \) is the system-level junction to ambient thermal resistance. It can be estimated from thermal modeling or measurements in the system.

The device thermal resistance depends strongly on the surrounding PCB layout and can be improved by providing a heat sink of surrounding copper ground. The addition of backside copper with thermal vias, stiffeners, and other enhancements can also help reduce thermal resistance.

Table 7 shows the simulated thermal resistance of the RTQ2822A/B which is mounted on PCB with difference tack-up and copper thickness. The layout of thermal model refers to the RTQ2822A/B evaluation board.

Table 7. Simulated Thermal Resistance with Difference Tack-Up and Copper Thickness

<table>
<thead>
<tr>
<th>Simulated ( \theta_{JA} )</th>
<th>( \theta_{JA} ) (°C/W)</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>4 Layer with 1oz copper</td>
<td>40</td>
</tr>
<tr>
<td>2 Layer with 1oz copper</td>
<td>52.5</td>
</tr>
</tbody>
</table>

As an example, consider the case when the RTQ2822A/B is used in applications where \( V_{IN} = 12V, I_{OUT} = 12A, f_{SW} = 800kHz, V_{OUT} = 1.2V. \)

The efficiency at 1.2V, 12A is 84% by using WE-744311068 (0.68μH, 3.1mΩ DCR) as the inductor and measured at room temperature. The core loss 0.125W can be obtained from its website. In this case, the power dissipation of the RTQ2822A/B is

\[ P_{D,RT} = \frac{1 - \eta}{\eta} \times P_{OUT} - \left( \frac{f}{\theta_{JA(EFFECTIVE)}} \times DCR + P_{CORE} \right) = 2.17W \]

Considering the \( \theta_{JA(EFFECTIVE)} \) is 33.6°C/W by using the RTQ2822A/B evaluation board with 4 layers PCB and 2oz copper thickness, the junction temperature of the regulator operating in a 25°C ambient temperature is approximately:

\[ T_J = 2.17W \times 33.6°C/W + 25°C = 98°C \]

Layout Guideline

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the RTQ2822A/B:

- Four-layer or six-layer PCB with maximum ground plane is strongly recommended for good thermal performance.
- Keep the traces of the main current paths wide and short.
- VIN pins should have equal input capacitors on each side of IC. Place these input capacitors as close to VIN pins as possible.
- Place the VCC decoupling capacitor, \( C_{VCC} \), as close to VCC pin as possible.
- Place bootstrap capacitor, \( C_{BOOT} \), as close to IC as possible. Routing the trace with width of 20mil or wider.
- Place multiple vias under the device near VIN and PGND and near input capacitors to reduce parasitic inductance and improve thermal performance. To keep thermal resistance low, extend the ground plane as much as possible, and add thermal vias under and near the RTQ2822A/B to additional ground planes within the circuit board and on the bottom side.
- The high frequency switching nodes, SW and BOOT, should be as small as possible. Keep analog components away from the SW and BOOT nodes.
- Connect the feedback sense network behind via of output capacitor.
- Place the feedback components R1/R2/C_{FF} near the IC.
- The ground connection between analog ground and power ground should be close to IC to minimize the ground current loops. If there is only one ground plane, it should keep enough isolation between analog return signals and high power signals.

Figure 16 is the layout example which uses 3"x3" (76mm x76mm), four-layer PCB with 2oz copper.
Power Good Indicator
Open-Drain Output.

Keep sensitive components away from this C8.

Input capacitor must be placed as close to IC VIN-GND as possible.

The feedback components must be connected as close to the device as possible.

Add extra vias for thermal consideration.

SW should be connected to inductor by wide and short trace. Keep sensitive components away from this trace.
