Phase-Cut Dimmable Primary-Side Regulation LED Driver Controller with Active PFC

General Description
The RT7310 is a high power factor constant current LED driver which is optimized for the compatibility with phase-cut dimmers. It supports high power factor across a wide range of line voltages, and it drives the converter in the Quasi-Resonant (QR) mode to achieve higher efficiency. By using Primary Side Regulation (PSR), RT7310 controls the output current accurately without a shunt regulator and an opto-coupler at the secondary side, reducing the external component count, the cost, and the volume of the driver board.

The RT7310 supports phase-cut dimmers, including leading-edge (TRIAC) and trailing-edge dimmers. RT7310 embeds comprehensive protection functions for robust designs, including LED open circuit protection, LED short circuit protection, output diode short-circuit protection, VDD Under-Voltage Lockout (UVLO), VDD Over-Voltage Protection (OVP), Over-Temperature Protection (OTP), and cycle-by-cycle current limitation.

Features
- Supporting Phase-Cut Dimmers
- Tight LED Current Regulation
- No Opto-Coupler and TL431 Required
- Power Factor Correction (PFC)
- Quasi-Resonant
- Maximum/Minimum Switching Frequency Clamping
- Maximum/Minimum On-Time Limitation
- Wide VDD Range (up to 25V)
- Multiple Protection Features:
  - LED Open-Circuit Protection
  - LED Short-Circuit Protection
  - Output Diode Short-Circuit Protection
  - VDD Under-Voltage Lockout
  - VDD Over-Voltage Protection
  - Over-Temperature Protection
  - Cycle-by-Cycle Current Limitation

Application
- Phase-Cut Dimmable LED luminaries

Simplified Application Circuit

Flyback Converter

Tapped-Inductor Buck-Boost Converter
RT7310

Ordering Information

RT7310

- Package Type
  - E : SOT-23-6

- Lead Plating System
  - G : Green (Halogen Free and Pb Free)

Marking Information

3K= : Product Code
DNN : Date Code

Note:

Richtek products are:

- RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- Suitable for use in SnPb or Pb-free soldering processes.

**Operation**

**Critical-Conduction Mode (CRM) with Constant On-Time Control**

Figure 1 shows a typical flyback converter with input voltage ($V_{IN}$). When main switch $Q_1$ is turned on with a fixed on-time ($t_{ON}$), the peak current ($I_{L\_PK}$) of the magnetic inductor ($L_m$) can be calculated by the following equation:

$$I_{L\_PK} = \frac{V_{IN} \times t_{ON}}{L_m}$$

When the converter operates in CRM with constant on-time control, the envelope of the peak inductor current will follow the input voltage waveform with in-phase. Thus, high power factor can be achieved, as shown in Figure 2.

If the input voltage is the output voltage of the full-bridge rectifier with sinusoidal input voltage ($V_{IN\_PK} \sin(\theta)$), the inductor peak current ($I_{L\_PK}$) can be expressed as the following equation:

$$I_{L\_PK} = \frac{V_{IN\_PK} \times |\sin(\theta)| \times t_{ON}}{L_m}$$

---

**Figure 1.** Typical Flyback Converter

**Figure 2.** Inductor Current of CRM with Constant On-Time Control
Primary-Side Constant-Current Regulation

RT7310 needs no shunt regulator and opto-coupler at the secondary side to achieve the output current regulation. Figure 3 shows several key waveforms of a conventional flyback converter in Quasi-Resonant (QR) mode, in which \( V_{AUX} \) is the voltage on the auxiliary winding of the transformer.

![Figure 3. Key Waveforms of a Flyback Converter](image)

Voltage Clamping Circuit

RT7310 provides a voltage clamping circuit at ZCD pin since the voltage on the auxiliary winding is negative when the main switch is turned on. The lowest voltage on ZCD pin is clamped near zero to prevent the IC from being damaged by the negative voltage. Meanwhile, the sourcing ZCD current \( (I_{ZCD\_SH}) \), flowing through the upper resistor \( (R_{ZCD\_T}) \), is sampled and held to be a line-voltage-related signal for propagation delay compensation. RT7310 embeds the programmable propagation delay compensation through CS pin. A sourcing current \( I_{CS} \) (equal to \( I_{ZCD\_SH} \times K_{PC} \)) applies a voltage offset \( (I_{CS} \times R_{PC}) \) which is proportional to line voltage on CS to compensate the propagation delay effect. Thus, the total power limit or output current can be equal at high and low line voltage.

Quasi-Resonant Operation

For improving converter’s efficiency, RT7310 detects valleys of the Drain-to-Source voltage \( (V_{DS}) \) of main switch and turns it on near the selected valley. For the valley detections, a pulse of the “valley signal” is generated after a 500ns (typ.) delay time which starts at which the voltage \( (V_{ZCD}) \) on ZCD pin goes down and reaches the voltage threshold \( (V_{ZCD\_T}, 0.4V \text{ typ.}) \). During the rising of the \( V_{ZCD} \), the \( V_{ZCD} \) must reach the voltage threshold \( (V_{ZCD\_A}, 0.5V \text{ typ.}) \). Otherwise, no pulse of the “valley signal” is generated. Moreover, if the timing when the falling \( V_{ZCD} \) reaches \( V_{ZCD\_T} \) is not later than a mask time \( (t_{MASK}, 2\mu s \text{ typ.}) \) then the valley signal will be masked and regards as no valley, as shown in Figure 4.

![Figure 4. Valley Signal Generating Method](image)

Figure 5 illustrates how valley signal triggers PWM. If no valley signal detected for a long time, the next PWM is triggered by a starter circuit at end of the interval \( (t_{START}, 75\mu s \text{ typ.}) \) which starts at the rising edge of the previous PWM signal. A blanking time \( (t_{S(MIN)}, 8.5\mu s \text{ typ.}) \), which starts at the rising edge of the previous PWM signal, limits minimum switching period. When the \( t_{S(MIN)} \) interval is on-going, all of valley signals are not allowed to trigger the next PWM signal. After the end of the \( t_{S(MIN)} \) interval, the coming valley will trigger the next PWM signal. If one or more valley signals are detected during the \( t_{S(MIN)} \) interval and no valley is detected after the end of the \( t_{S(MIN)} \) interval, the next PWM signal will be triggered automatically at end of the \( t_{S(MIN)} + 5\mu s \text{ (typ.)} \).
LED Short-Circuit Protection
LED short-circuit protection can be achieved by cycle-by-cycle current limitation, and it will be auto-restarted when the output is recovered.

Output Diode Short-Circuit Protection
When the output diode is damaged as short-circuit, the transformer will be led to magnetic saturation and the main switch will suffer from a high current stress. To avoid the above situation, an output diode short-circuit protection is built-in. When CS voltage $V_{CS}$ exceeds the threshold ($V_{CS\_SD}$ 1.5 typ.) of the output diode short-circuit protection, RT7310 will shut down the PWM output (GD pin) in few cycles to prevent the converter from damage.

VDD Under-Voltage Lockout (UVLO) and Over-Voltage Protection (VDD OVP)
RT7310 will be enabled when VDD voltage ($V_{DD}$) exceeds rising UVLO threshold ($V_{TH\_ON}$, 16V typ.) and disabled when $V_{DD}$ is lower than falling UVLO threshold ($V_{TH\_OFF}$, 9V typ.).
When $V_{DD}$ exceeds its over-voltage threshold ($V_{OVP}$, 27V typ.), the PWM output of RT7310 is shut down. It will be auto-restarted when the $V_{DD}$ is recovered to a normal level.

Over-Temperature Protection (OTP)
The RT7310 provides an internal OTP function to protect the controller itself from suffering thermal stress and permanent damage. It is not suggested to use the function as precise control of over temperature. Once the junction temperature is higher than the OTP threshold ($T_{SD}$, 150°C typ.), the controller will shut down until the temperature cools down by 30°C (typ.).

Figure 5. PWM Triggered Method

Protections

LED Open-Circuit Protection
In an event of output open circuit, the converter will be shut down to prevent being damaged. Once the LED is open-circuit, the output voltage and $V_{ZCD}$ will rise. When the sample-and-hold ZCD voltage ($V_{ZCD\_SH}$) exceeds its OV threshold ($V_{ZCD\_OVP}$, 3.1V typ.), output OVP will be activated and the PWM output (GD pin) will be forced low to turn off the main switch.
Absolute Maximum Ratings (Note 1)
- VDD Supply Voltage, $V_{DD}$: $-0.3\text{V to 30V}$
- GD to GND Voltage, $V_{GD}$: $-0.3\text{V to 20V}$
- CS, ZCD, COMP to GND Voltage: $-0.3\text{V to 6V}$
- Power Dissipation, $P_D @ T_A = 25^\circ\text{C}$
  - SOT-23-6: $0.42\text{W}$
- Package Thermal Resistance (Note 2)
  - SOT-23-6, $\theta_{JA}$: $235.6^\circ\text{C/W}$
- Junction Temperature: $150^\circ\text{C}$
- Lead Temperature (Soldering, 10 sec.): $260^\circ\text{C}$
- Storage Temperature Range: $-65^\circ\text{C to 150^\circC}$
- ESD Susceptibility (Note 3)
  - Human Body Model: $2\text{kV}$
  - Machine Model: $200\text{V}$

Recommended Operating Conditions (Note 4)
- Supply Input Voltage, $V_{DD}$: $12\text{V to 25V}$
- COMP Voltage, $V_{COMP}$: $0.7\text{V to 4.3V}$
- Ambient Temperature Range: $-40^\circ\text{C to 85^\circC}$
- Junction Temperature Range: $-40^\circ\text{C to 125^\circC}$

Electrical Characteristics
($V_{DD} = 15\text{V}, T_A = 25^\circ\text{C}$, unless otherwise specification)

**Note 1.** Stresses beyond those listed “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

**Note 2.** $\theta_{JA}$ is measured in the natural convection at $T_A = 25^\circ C$ on a low effective two layer thermal conductivity test board of JEDEC 51-3 thermal measurement standard.

**Note 3.** Devices are ESD sensitive. Handling precaution recommended.

**Note 4.** The device is not guaranteed to function outside its operating conditions.

**Note 5.** Guaranteed by Design.

Application Information

Output Current Setting

Considering the conversion efficiency, the programmed DC level of the average output current ($I_{OUT}(t)$) can be derived as:

$$I_{OUT,CC} = \frac{1}{2} \frac{N_P}{N_S} \frac{K_{CC} \times CTR_{TX1}}{R_{CS}}$$

$$CTR_{TX1} = \frac{I_{SEC,PK}}{I_{PRI,PK}} \times \frac{N_S}{N_P},$$

in which $CTR_{TX1}$ is the current transfer ratio of the transformer $TX1$, $I_{SEC,PK}$ is the peak current of the secondary side, and $I_{PRI,PK}$ is the peak current of the primary side. $CTR_{TX1}$ can be estimated to be 0.9.

According to the above parameters, current sense resistor $R_{CS}$ can be determined as the following equation:

$$R_{CS} = \frac{1}{2} \frac{N_P}{N_S} \frac{K_{CC}}{I_{OUT,CC}} \times CTR_{TX1}$$

Propagation Delay Compensation Design

The $V_{CS}$ deviation ($\Delta V_{CS}$) caused by propagation delay effect can be derived as:

$$\Delta V_{CS} = \frac{V_{IN} \cdot t_d \cdot R_{CS}}{L_m},$$

in which $t_d$ is the delay period which includes the propagation delay of RT7310 and the turn-off transition of the main MOSFET. The sourcing current from CS pin of RT7310 ($I_{CS}$) can be expressed as:

$$I_{CS} = K_{PC} \cdot V_{IN} \cdot \frac{N_A}{N_P} \cdot \frac{1}{R_{ZCD1}}$$

where $N_A$ is the turns number of auxiliary winding.

$R_{PC}$ can be designed by:

$$R_{PC} = \frac{\Delta V_{CS}}{I_{CS}} = \frac{t_d \cdot R_{CS} \cdot R_{ZCD1}}{L_m} \cdot K_{PC} \cdot \frac{N_P}{N_A}$$

Minimum On-Time Setting

RT7310 limits a minimum on-time ($t_{ON(MIN)}$) for each switching cycle. The $t_{ON(MIN)}$ is a function of the sample-and-hold ZCD current ($I_{ZCD\_SH}$) as following:

$$t_{ON(MIN)} \cdot I_{ZCD\_SH} = 405p \cdot sec \cdot A \ (typ.)$$

$I_{ZCD\_SH}$ can be expressed as:

$$I_{ZCD\_SH} = \frac{V_{IN} \cdot N_A}{R_{ZCD1} \cdot N_P}$$

Thus, $R_{ZCD1}$ can be determined by:

$$R_{ZCD1} = \frac{t_{ON(MIN)} \cdot V_{IN} \cdot N_A}{405p \cdot N_P} \ (typ.)$$

In addition, the current flowing out of ZCD pin must be lower than 2.5mA (typ.). Thus, the $R_{ZCD1}$ is also determined by:

$$R_{ZCD1} > \frac{\sqrt{2} \cdot V_{AC(MAX)}}{2.5mA} \cdot \frac{N_A}{N_P}$$

where the $V_{AC(MAX)}$ is maximum input AC voltage.

Output Over-Voltage Protection Setting

Output OVP is achieved by sensing the knee voltage on the auxiliary winging. It is recommended that output OV level ($V_{O,OVP}$) is set at 120% of nominal output voltage ($V_O$). Thus, $R_{ZCD1}$ and $R_{ZCD2}$ can be determined by the equation as:

$$V_O \cdot \frac{N_A}{N_S} \cdot \frac{R_{ZCD2}}{R_{ZCD1} + R_{ZCD2}} \cdot 120\% = 3.1V \ (typ.)$$

Thermal Considerations

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula:

$$P_D(MAX) = \frac{(T_{J(MAX)} - T_A)}{\theta_{JA}}$$

Where $T_{J(MAX)}$ is the maximum junction temperature, $T_A$ is the ambient temperature, and $\theta_{JA}$ is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is 125°C. The junction to ambient thermal resistance, $\theta_{JA}$, is layout dependent. For SOT-23-6 packages, the thermal resistance, $\theta_{JA}$, is 235.6°C/W on a standard JEDEC 51-3 two-layer thermal test board. The maximum power dissipation is limited to 1.2W.
dissipation at $T_A = 25^\circ C$ can be calculated by the following formula:

$$P_{D(MAX)} = (125^\circ C - 25^\circ C) / (235.6^\circ C/W) = 0.42W$$

for SOT-23-6 package

The maximum power dissipation depends on the operating ambient temperature for fixed $T_J(MAX)$ and thermal resistance, $\theta_{JA}$. The derating curve in Figure 6 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

![Derating Curve of Maximum Power Dissipation](image)

**Figure 6. Derating Curve of Maximum Power Dissipation**

### Layout Considerations

A proper PCB layout can abate unknown noise interference and EMI issue in the switching power supply. Please refer to the guidelines when designing a PCB layout for switching power supply:

- The current path(1) from input capacitor, transformer, MOSFET, $R_{CS}$ return to input capacitor is a high frequency current loop. The path(2) from GD pin, MOSFET, $R_{CS}$ return to input capacitor is also a high frequency current loop. They must be as short as possible to decrease noise coupling and kept a space to other low voltage traces, such as IC control circuit paths, especially. Besides, the path(3) between MOSFET ground(b) and IC ground(d) is recommend to be as short as possible, too.

- The path(4) from RCD snubber circuit to MOSFET is a high switching loop. Keep it as small as possible.

- It is good for reducing noise, output ripple and EMI issue to separate ground traces of input capacitor(a), MOSFET(b), auxiliary winding(c) and IC control circuit(d). Finally, connect them together on input capacitor ground(a). The areas of these ground traces should be kept large.

- Placing bypass capacitor for abating noise on IC is highly recommended. The capacitors $C_{COMP}$, $C_{ZCD}$, and $C_{CS}$ should be placed as close to controller as possible.

- To minimize parasitic trace inductance and EMI, minimize the area of the loop connecting the secondary winding, the output diode, and the output filter capacitor. In addition, apply sufficient copper area at the anode and cathode terminal of the diode for heat-sinking. It is recommended to apply a larger area at the quiet cathode terminal. A large anode area will induce high-frequency radiated EMI.
