High Voltage High Multiple-Topology Current LED Driver

General Description
The RT8477A is a current mode PWM controller designed to drive an external MOSFET for high current LED applications with wide input voltage (4.5V to 50V) and output voltage (up to 50V) ranges. With internal 380kHz operating frequency, the size of the external PWM inductor and input/output capacitors can be minimized. High efficiency is achieved by a 100mV current sensing control. LED Dimming control can be done by analog.

The RT8477A is now available in the SOP-8 (Exposed Pad) package.

Features
- Support Multiple-Topologies (Buck/Boost/Buck-Boost)
- High Voltage: $V_{IN}$ up to 50V, $V_{OUT}$ up to 50V
- 380kHz Fixed Switching Frequency
- Analog or PWM Control Signal for LED Dimming
- Internal Soft-Start to Avoid Inrush Current
- Under-Voltage Lockout
- Thermal Shutdown

Applications
- Desk Lights and Room Lighting
- Industrial Display Backlight

# Function Block Diagram

![Function Block Diagram](image)
Operation

The RT8477A is a current mode PWM controller designed to drive an external MOSFET for high current LED applications. This device uses a fixed frequency, current-mode control scheme to provide excellent line and load regulation.

The control loop has a current sense amplifier which senses the voltage between the ISP and ISN pins.

A PWM comparator then turns off the external power switch when the sensed power switch current exceeds the internal compensated voltage. The power switch will not be reset by the oscillator clock in each cycle. If the comparator does not turn off the switch in a cycle, the power switch will be on for more than a full switching period until the comparator is tripped. In this manner, the programmed voltage across the sense resistor is regulated by the control loop.

The current through the sense resistor is set by the programmed voltage and the sense resistance. The voltage across the sense resistor can be programmed by the analog or digital signal at the CTL pin with good dimming linearity. The max sense threshold of 100mV can be obtained with CTL pin voltage greater than 2V (max dimming point). The sense threshold is intentionally forced to zero by an internal comparator when the CTL pin voltage is less than around 0.33V (min dimming point). Because of that, the actual sense threshold right before cut off may vary from part to part over process variation.

The RT8477A provides protection functions which include over-temperature, and switch current limit to prevent abnormal situations.

### Absolute Maximum Ratings

- **Stresses beyond those listed** "Absolute Maximum Ratings" **may cause permanent damage to the device.** These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. **Exposure to absolute maximum rating conditions may affect device reliability.**

### Note 2.
If connected with a 20kΩ serial resistor, CTL can go up to 40V.

### Note 3.
θJA is measured at T_A = 25°C on a high effective thermal conductivity four-layer test board per JEDEC 51-7. θJC is measured at the exposed pad of the package.

### Note 4.
Devices are ESD sensitive. Handling precaution is recommended.

### Note 5.
The device is not guaranteed to function outside its operating conditions.

### Note 6.
When the natural maximum duty cycle of the switching frequency is reached, the switching cycle will be skipped (not reset) as the operating condition requires to effectively stretch and achieve higher on cycle than the natural maximum duty cycle set by the switching frequency.

### Note 7.
Guaranteed by design, not subjected to production test.

Typical Application Circuit

Buck Configuration

Boost Configuration

Note:
1. \( V_{\text{IN}}, V_{\text{ISP}}, V_{\text{ISN}} < 50 \text{V} \)
2. \( V_{\text{LED}} \): the voltage across the LED string
3. \( V_z \): Zener diode breakdown voltage
Buck-Boost Configuration

Note:
1. \( V_{ISP}, V_{ISN} < 50 \text{V} \)
2. \( V_{LED} \): the voltage across the LED string
3. \( V_z \): Zener diode breakdown voltage
Typical Operating Characteristics

**Efficiency vs. Input Voltage**

- Buck, LED Current = 2A, L = 22μH
- VOUT = 21V
- VOUT = 18V
- VOUT = 15V
- VOUT = 12V
- VOUT = 9V
- VOUT = 6V

**Supply Current vs. VCC**

**LED Current vs. VCTL**

- LED Current = 300mA, LED = 6pcs

**ISP - ISN Threshold vs. Temperature**

- ISP - ISN Threshold (mV)
- VCC = 24V

**Frequency vs. VCC**

**Power On from VIN**

- VIN = 30V, IOUT = 2A, LED = 42pcs, L = 47μH
- Time (2.5ms/Div)
- VOUT (10V/Div)
- IOUT (2A/Div)
Power Off from VIN

- **VIN** (20V/Div)
- **VOUT** (10V/Div)
- **IOUT** (2A/Div)

VIN = 30V, IOUT = 2A, LED = 42pcs, L = 47μH

Time (25ms/Div)
Application Information

The RT8477A is a current mode PWM controller designed to drive an external MOSFET for high current LED applications. This device uses a fixed frequency, current mode control scheme to provide excellent line and load regulation. The control loop has a current sense amplifier which senses the voltage between the ISP and ISN pins. The power switch will not be reset by the oscillator clock in each cycle. If the comparator does not turn off the switch in a cycle, the power switch will be on for more than a full switching period until the comparator is tripped. In this manner, the programmed voltage across the sense resistor is regulated by the control loop.

Frequency Compensation

The RT8477A has an external compensation pin, allowing the loop response to be optimized for specific applications. An external resistor in series with a capacitor is connected from the VC pin to GND to provide a pole and a zero for proper loop compensation. The typical value for the RT8477A is 10k and 3.3nF.

LED Current Setting

The LED current can be calculated by the following equation:

\[ I_{\text{LED(MAX)}} = \frac{V(\text{ISP} - \text{ISN})}{R1} \]

where \( V(\text{ISP} - \text{ISN}) \) is the voltage between ISP and ISN (100mV typ. if CTL dimming is not applied) and the R1 is the resister between ISP and ISN.

Sense Resistor Selection

The resistor, R2, between the Source of the external N-MOSFET and GND should be selected to provide adequate switch current to drive the application without exceeding the current limit threshold set by the SENSE pin sense threshold of RT8477A. The Sense resistor value can be calculated according to the formula below:

\[ R2 = \frac{\text{Current Limit Threshold Minimum Value}}{I_{\text{OCP}}} \]

where \( I_{\text{OCP}} \) is about 1.33 to 1.5 times of inductor peak current \( I_{\text{PEAK}} \).

The placement of R2 should be close to the source of the N-MOSFET and the IC GND of the RT8477A. The SENSE pin input to RT8477 should be a Kelvin sense connection to the positive terminal of R2.

Over-Temperature Protection

The RT8477A has Over-Temperature Protection (OTP) function to prevent the excessive power dissipation from overheating. The OTP function will shut down switching operation when the die junction temperature exceeds 150°C. The chip will automatically start to switch again when the die junction temperature cools off.

Inductor Selection

The converter operates in discontinuous conduction mode when the inductance value is less than the value \( L_{\text{BCM}} \). With an inductance greater than \( L_{\text{BCM}} \), the converter operates in Continuous Conduction Mode (CCM). The inductance \( L_{\text{BCM}} \) is determined by the following equations.

For Buck application:

\[ L_{\text{BCM}} = \frac{V_{\text{OUT}}}{2 \times I_{\text{OUT}} \times f} \times \left( \frac{V_{\text{IN}} - V_{\text{OUT}}}{V_{\text{IN}}} \right) \]

For Boost application:

\[ L_{\text{BCM}} = \frac{V_{\text{OUT}} - V_{\text{IN}}}{2 \times I_{\text{OUT}} \times f} \times \left( \frac{V_{\text{IN}}}{V_{\text{OUT}}} \right)^2 \]

For Buck-Boost application:

\[ L_{\text{BCM}} = \frac{V_{\text{OUT}}}{2 \times I_{\text{OUT}} \times f} \times \left( \frac{V_{\text{IN}}}{V_{\text{IN}} + V_{\text{OUT}}} \right)^2 \]

where

- \( V_{\text{OUT}} \) = output voltage.
- \( V_{\text{IN}} \) = input voltage.
- \( f \) = operating frequency.
- \( I_{\text{OUT}} \) = LED current.

Choose an inductance based on the operating frequency, input voltage and output voltage to provide a current mode ramp signal during the MOSFET on period for PWM control loop regulation. The inductance also determines the inductor ripple current. Operating the converter in CCM is recommended, which will have the smaller inductor ripple current and hence the less conduction losses from all converter components.
As a design example, to design the peak to peak inductor ripple to be ±30% of the output current, the following equations can be used to estimate the size of the needed inductance:

For Buck application:
\[
L = \frac{V_{OUT}}{2 \times 0.3 \times I_{OUT} \times f} \times \left( \frac{V_{IN} - V_{OUT}}{V_{IN}} \right)
\]

For Boost application:
\[
L = \frac{V_{OUT} - V_{IN}}{2 \times 0.3 \times I_{OUT} \times f} \times \left( \frac{V_{IN} - V_{OUT}}{V_{OUT}} \right)^2
\]

For Buck-Boost application:
\[
L = \frac{V_{OUT}}{2 \times 0.3 \times I_{OUT} \times f} \times \left( \frac{V_{IN}}{V_{IN} + V_{OUT}} \right)^2
\]

The inductor must also be selected with a saturation current rating greater than the maximum inductor current during normal operation. The maximum inductor current can be calculated by the following equations.

For Buck application:
\[
I_{PEAK} = I_{OUT} + \frac{V_{OUT}}{2 \times L \times f} \times \left( \frac{V_{IN} - V_{OUT}}{V_{IN}} \right)
\]

For Boost application:
\[
I_{PEAK} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta} + \frac{V_{OUT} - V_{IN}}{2 \times L \times f} \times \left( \frac{V_{IN}}{V_{OUT}} \right)^2
\]

For Buck-Boost application:
\[
I_{PEAK} = \frac{V_{OUT} + V_{IN} \times \eta}{V_{IN} \times \eta} \times I_{OUT} + \frac{V_{OUT}}{2 \times L \times f} \times \left( \frac{V_{IN}}{V_{IN} + V_{OUT}} \right)^2
\]

where \( \eta \) is the efficiency of the power converter.

**Capacitor Selection**

The input capacitor reduces current spikes from the input supply and minimizes noise injection to the converter. For most RT8477A applications, a 4.7 μF ceramic capacitor is sufficient. A value higher or lower may be used depending on the noise level from the input supply and the input current to the converter. In Buck application, the output capacitor is typically ceramic and selection is mainly based on the output voltage ripple requirements. The output ripple, \( \Delta V_{OUT} \), is determined by the following equation:
\[
\Delta V_{OUT} \leq \Delta L \times \left[ ESR + \frac{1}{8 \times f \times C_{OUT}} \right]
\]

**Thermal Considerations**

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula:
\[
P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}
\]

where \( T_{J(MAX)} \) is the maximum junction temperature, \( T_A \) is the ambient temperature, and \( \theta_{JA} \) is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is 125°C. The junction to ambient thermal resistance, \( \theta_{JA} \), is layout dependent. For SOP-8 (Exposed Pad) package, the thermal resistance, \( \theta_{JA} \), is 30.6°C/W on a standard JEDEC 51-7 four-layer thermal test board. The maximum power dissipation at \( T_A = 25^\circ C \) can be calculated by the following formula:
\[
P_{D(MAX)} = (125^\circ C - 25^\circ C) / (30.6^\circ C/W) = 3.26W \]

The maximum power dissipation depends on the operating ambient temperature for fixed \( T_{J(MAX)} \) and thermal resistance, \( \theta_{JA} \). The derating curve in Figure 1 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.
Figure 1. Derating Curve of Maximum Power Dissipation

Layout Considerations
PCB layout is very important when designing power switching converter circuits. Some recommended layout guide lines are as follows:

- The power components M1, L1, D1 and C4 must be placed as close to each other as possible to reduce the ac current loop area. The PCB trace between power components must be as short and wide as possible due to large current flow through these traces during operation.
- Place M1, L1 and D1 as close to each other as possible. The trace should be as short and wide as possible.
- The input capacitor C6 must be placed as close to VCC pin as possible.

Figure 2. PCB Layout Guide

VIN power trace to ISP must be wide and short.

Keep the ISP and ISN with The Kelvin sense connection.

Locate input capacitor as close VCC as possible.

Power trace must be wide and short when compared to the normal trace.

Locate the compensation Components to VC pin as close as possible.

Normal trace.
